## Waushter

## Dear Water Warriors,

Reduce, reuse n recycle $3 \mathrm{R}^{\prime}$ s in context of water motivated us to apply technology and resulted in disconnect from nature.

Actually, a single $R$, Respect is something that WATER always needed.

'Waughter' is an attempt to bring the dignity to the reborn water produced out of scientific efforts and adding to available WATER.

Urmi Patel

## Question 1:

A Typical waste water has pH of 6.7 and your task is to raise the pH to 7.5. That's it? Can you calculate quantity of NaOH needed to raise it to 7.5 ?

If you think you can, as you know $\mathrm{pH}=-\log \left[\mathrm{H}^{+}\right]$, don't get surprised to know you are wrong. The natural water contains $\mathrm{CO}_{2}$ that can buffer $\mathrm{H}^{+}$(Refer Image 1.1). So, one should use a different equation of pH in this case as hereunder:
$\mathrm{pH}=6.3+\log \left(\mathrm{HCO}_{3}{ }^{-} \text {as } \mathrm{CaCO}_{3} \div \mathrm{CO}_{2} \text { as } \mathrm{CO}_{2}\right)_{(E q .1)}$

This brings additional problem to us. How much is $\mathrm{HCO}_{3}$ in our water? To know that, please visit lab and test two parameters:

## Alkalinity

The alkalinity in water indicates the quantities of hydroxide, carbonate and bicarbonate in water. Water may contain either of the 2 never all 3.

The alkalinity of water is determined using two indicators. Phenolphthalein Indicator gives the $P$ Alkalinity (End Point 8.3 pH ) and Methyl Orange Indicator yields the M Alkalinity (End Point 4.2 pH ).

In this inaugural issue we focus on the "The Chemistry of Water" and try to make it useful to reader for the day-today work with water.
(2) How much Acid or Alkali to dose to raise /reduce pH ?
(2) Why $\mathrm{H}_{2} \mathrm{O}$ with small molecular weight is passing but NaCl with 58 Molecular weight is rejected by RO membranes?
(2) Buffering of $\mathrm{CO}_{2} \& \mathrm{NH}_{3}$
(2) Definitions \& Ionic Balance
( Significance of $\mathrm{CaCO}_{3}$
CO2

Image 1.1 : The pH and $\mathrm{HCO} 3, \mathrm{CO}$ Relation

M alkalinity is also called Total alkalinity.
$\mathrm{M}=\mathrm{HCO}_{3}^{-}+\mathrm{CO}_{3}^{--}+\mathrm{OH}^{-}$
$\mathrm{P}=1 / 2 \mathrm{CO}_{3}^{-}+\mathrm{OH}^{-}$

If we apply modern maths on above we can understand below table:

| Alkalinity Relationship |  |  |  |
| :--- | :--- | :--- | :--- |
| Relation | Bicarbonate HCO3 | Carbonate C03 $^{-}$ | HydroxylOH $^{-}$ |
| $P=0$ | $M$ | 0 | 0 |
| $M=P$ | 0 | 0 | $M$ |
| $M=2 P$ | 0 | $M$ | 0 |
| $M<2 P$ | 0 | $2(M-P)$ | $2 P-M$ |
| $M>2 P$ | $M-2 P$ | $2 P$ | 0 |

The Lab technician tests water and reports M as 200 $\mathrm{mg} / \mathrm{l}$ and P as 0 . What it means is $\mathrm{HCO}_{3}{ }^{-}$is $200 \mathrm{mg} / \mathrm{l}$.

Now if we put this value in Eq. 1 and solve it for $\mathrm{CO}_{2}$, we will get:
$\mathrm{CO}_{2}=79.62 \mathrm{mg} / \mathrm{l}$ as $\mathrm{CO}_{2}$

In the event Acid or Alkali dosing to Reduce or Raise pH , we should understand what's happening to our equation. By Dosing $X \mathrm{mg} / \mathrm{I}$ (ppm) Alkali.

Alkali : $\uparrow \mathrm{HCO}_{3}{ }^{-}, ~ \downarrow \mathrm{CO}_{2}$
Acid : $\uparrow \mathrm{CO}_{2}, \downarrow \mathrm{HCO}_{3}{ }^{-}$
$\mathrm{pH}=6.3+\log \left\{\left[\left(\mathrm{HCO}_{3}{ }^{-}+\mathrm{X}\right)\right.\right.$ as $\left.\mathrm{CaCO}_{3}\right] \div\left[\left(\mathrm{CO}_{2}-0.88^{*} \mathrm{X}\right)\right.$ as $\left.\left.\left.\mathrm{CO}_{2}\right)\right]\right\}$ (Eq. 1.1.)

| Sr No | Parameter | Unit | Value |
| :---: | :---: | :---: | :---: |
| 1 | pH Actual | - | 6.7 |
| 2 | pH Required | - | 7.5 |
| 3 | M Alkalinity | $\mathrm{mg} / \mathrm{l}$ as CaCO 3 | 200 |
| 4 | P Alka linity | mg/l as CaCO3 | 0 |
| 5 | HCO3 | $\mathrm{mg} / \mathrm{l}$ as CaCO 3 | 200 |
| 6 | CO3 | $\mathrm{mg} / \mathrm{l}$ as CaCO 3 | 0 |
| 7 | OH | $\mathrm{mg} / \mathrm{l}$ as CaCO 3 | 0 |
| 8 | CO2 | $\mathrm{mg} / \mathrm{l}$ as CO 2 | 79.62 |
| 11 | Dose of $\mathrm{NaOH} / \mathrm{HCL}$ | $\mathrm{mg} / \mathrm{l}$ as CaCO 3 | 71.05 |
| 12 | Dose as Such Alkali | $\mathrm{mg} / \mathrm{l}$ as NaOH | 56.84 |
| 13 | Dose as Such Acid | $\mathrm{mg} / \mathrm{l}$ as HCl | -53.28 |
|  | Available value |  |  |
|  | Desired |  |  |
|  | Fill after undersatnding M, P Relation |  |  |

A quick solution shall suggest that for our case we have to add $28.41 \mathrm{mg} / \mathrm{I} \mathrm{NaOH}$ to raise pH to 7.5 from 6.7 , if M Alkalinity is $200 \mathrm{mg} /$ land P Alkalinity is $0 \mathrm{mg} / \mathrm{l}$.

Now lets solve what was 0.88 .

## Question 2:

## If you have $\$ \mathbf{5}$, ₹10 and $€ 15$, how much money you have?

Well, you should know the conversion to bring them to a common unit as the answer shall be in \$, ₹ or €.

Similarly, in water chemistry the addition of impurities shall be done after converting it to a common unit of measurement.

| Look at a Material | $\mathrm{CaCO}_{3}$ |
| :--- | :--- |
| Molecular Weight | $=40+12+3 * 16$ |
|  | $=100$ |
| Valency | $=2$ |

Therefore,

Equivalent Weight $=$ Molecular Wt. $\div$ Valency

$$
\begin{aligned}
& =100 \div 2 \\
& =50
\end{aligned}
$$

Thus, all the dissolved impurities are converted into equivalent $\mathrm{CaCO}_{3}$ before any further work.

So if $\mathrm{CO}_{2}$ has a molecular weight of $12+2 * 16=44$, since valency of gas is considered 1 , the equivalent weight is 44.

Thus 0.88 is conversion of $\mathrm{CaCO}_{3}(50)$ into $\mathrm{CO}_{2}(44)$. CF to $\mathrm{CO}_{2}=44 / 55=\underline{0.88}$.

On similar lines,

To Convert as such of Ion to equivalent $\mathrm{CaCO}_{3}$, please multiply by:

| Chloride | $\mathrm{Cl}^{-}$ | $1.41(50 \div 35.5)$ |
| :--- | :--- | :--- |
| Sulphate | $\mathrm{SO}_{4}^{--}$ | $1.04(50 \div 48)$ |
| Nitrate | $\mathrm{NO}_{3}-$ | $0.81(50 \div 62)$ |
|  |  |  |
| Calcium | $\mathrm{Ca}^{++}$ | $2.50(50 \div 20)$ |
| Magnesium | $\mathrm{Mg}^{++}$ | $4.20(50 \div 12)$ |

## Definitions \& Ionic Balance

Let's have a look and image 1.2.
$\mathrm{H}, \mathrm{OH}$ in centre as Cation \& Anion is sign of Acidity or Basicity, if free. If bonded as in H-O-H it's Water.

Water contains some free space, not visible to naked eyes called Inter Molecular space (IMS). Impurities hidden in this space are termed dissolved, soluble.

Floating matter; Wood, plants, fibres, plastic, oil all remain on surface as their specific gravity is $<1$.

Gases may be dissolved (in IMS), remember term DO it's the $\mathrm{O}_{2}$ that is in IMS. Gases out of IMS are bubble and may stick to wall or come out in atmosphere.

Ions with + Ve charge are Cation and -Ve charge Anion.

## Hardness

$\mathrm{Ca}^{++} \& \mathrm{Mg}^{++}$ion and others in same column in periodic table ( $\mathrm{Be}^{++}, \mathrm{Sr}^{++}, \mathrm{Ba}^{++}$) have same characteristics. They tend to precipitate and stick to the surface causing scale.

As per rules of electroneutrality, ions though free entity must have a relation with counter ion to balance it's charge. One of the common most example of a relation is $\mathrm{Na}^{+} \& \mathrm{Cl}^{-}$.

Hardness that has (M-Alkalinity as balancing ion is Temporary and the one with balancing ion as EMA is termed Permanent. $\mathrm{Ca}^{++} \& \mathrm{Mg}^{++}$prefer M -Alkalinity and as long as M -alkalinity is available, all hardness would be temporary. Permanent hardness will appear only when Hardness > Alkalinity, here too alkalinity would love $\mathrm{Ca}^{++}$first and $\mathrm{Mg}^{++}$next.

## Equivalent Mineral Acidity (EMA)

$\mathrm{Cl}^{-}, \mathrm{SO}_{4}^{--} \& \mathrm{NO}_{3}{ }^{-}$are anions as they have -Ve Charge. Imagine their balancing ion is $\mathrm{Na}+$ and in that case they all appear like salt. $\mathrm{NaCl} \mathrm{Na}_{2} \mathrm{SO}_{4}$ and $\mathrm{NaNO}_{3}$ respectively.

In case $\mathrm{Na}^{+}$is replaced by $\mathrm{H}^{+}$ion, they will look like HCl $\mathrm{H}_{2} \mathrm{SO}_{4}$ and $\mathrm{HNO}_{3}$, the mineral acids. Thus, the anions that have potential to form mineral acids have a family name EMA.

Total Anion, therefore is sum of two differentiating anions 1. EMA \& 2. M - Alkalinity.

TA $=$ M-Alkalinity + EMA

Rules of electroneutrality means Total Anion should be equal to Total Anion (in terms of same unit ppm as $\mathrm{CaCO}_{3}$ ), we say;

Total Cation = Total Anion ; And that means we need to now calculate the balance monovalent ions ( $\mathrm{Na}^{+}, \mathrm{K}^{+}$etc) by subtraction:
$\mathrm{Na}^{+}+\mathrm{K}^{+}=$Total Cation - Total Hardness
$\mathrm{Fe}^{++}, \mathrm{Cu}^{++}$and other metallic ions are low in concentrations, and can be oxidized, precipitated and dealt like a suspended matter hence not calculated normally in ionic balance as a matter of simplicity.

| Gases: $\mathrm{CO} 2, \mathrm{O} 2, \mathrm{H} 2 \mathrm{~S}$ |  |
| :---: | :---: |
| Floating Matter : Wood Chips, Plants, Oil |  |
| Clay, Silt, Organic Matter, Turbidity |  |
| Colloids |  |
| $\mathrm{H}^{+}$ | $\mathrm{OH}^{-}$ |
| $\mathrm{Na}^{+} \mathrm{K}^{+}$ | $\mathrm{HCO}^{-} \mathrm{CO}^{-}$ |
| $\mathrm{Ca}^{++} \mathrm{Mg}^{++}$ | $\mathrm{Cl}^{-} \mathrm{SO}^{-{ }^{-1} \mathrm{NO}^{-}}$ |
| $\mathrm{Fe}^{++} \mathrm{Mn}^{++} \rightarrow 3 \mathrm{Val}$. | PO4 ${ }^{--1}$ |
| Silica, Sugar, Phenol |  |
| Organics, COD,BOD,TOC etc. | Micro Organisms |

Image 1.2 : Definition \& Ionic Balance

So, a good engineer will walk 11 steps on the water analysis report before doing anything, to be sure he/she is working in right direction.

```
Step 1 :Check Adequacy of Data
Step 2 : Convert Impurities to CaCO3, if not reported as CaCO3
Step 3 : Calculate EMA
Step 4 :Calculate Total Anion ( = EMA + M-Alkalinity)
Step 5 : Calculate Total Cation (TC = TA, H2O is Electro neutral)
Step 6 : Find Na+}+\mp@subsup{K}{}{+}=TC - Total Hardnes
Step 6A : If you get - Ve Value, it indicates error in report
Step 7 : Observe M and P Value
Step 8 : Report HCO3-, CO3-- and OH-
Step 9 : Observe Total Hardness and M-Alkalinity
Step 10: Report Temporary and Permanent Hardness
Step 11 : Report Sodium Alkalinity
```

## Volume 1 : Edition 1 - The Chemistry of Water

## Reverse Osmosis \& Chemistry:

This subject of salt behaviours needs explanation at fundamental levels.

Look at the table below:

| Molecule | Molecular Weight | Size |
| :---: | :---: | :---: |
| $\mathrm{H}_{2} \mathrm{O}$ | 18 | $\sim 2.75$ ANGSTROM |
| Na | 23 | Ionic Radius 154 pm |
| $\mathrm{Na}^{+}$ | 23 | Ionic Radius 102 pm |
| $\mathrm{F}^{-}$ | 35.5 | Ionic Radius 133 pm |

pm IS peta meter $1 \times 10^{-15}$

Wonder why the water is filleted across a composite polyamide membrane RO membrane with distributed pore size in the range of $3-10 \AA$, but $\mathrm{Na}^{+}$or $\mathrm{F}^{-}$which is at-least 1000 times smaller in size cannot?

The answer lies in understanding hydration.

Image 1.3 : Hydration of $\mathrm{Na}^{+}$in H 2 O

The ions that are hydrated cannot move alone; they must take the hydration shell fully as well as little bit of partially ordered zone when they move.

Furthermore, a single $\mathrm{Na}^{+}$can not pass alone even if opportunity exists, as we cannot have Charge transferring across membrane. Counter charge e.g. $\mathrm{Cl}^{-}$ shall also have the mood to go with $\mathrm{Na}^{+}$, this is very improbable and thus bulk of NaCl is rejected across RO membrane.

On different lines, find out why $\mathrm{NH}_{4}{ }^{+}, \mathrm{NO}_{3}{ }^{-}$is not rejected well on membranes but pass. Waughter is a wonder material and we consistently learn more.

## जल जीवन जननी !!

Vaishali Singh our summer intern, daughter of a farmer and an aspiring Chemical Engineer sow the seeds of this magazine; we wish her good luck !!

## Sanjeev Srivastava

 $3 w \cdot(5)$'Waughter'

Jal jeevan and Janni.. the word 'waughter' heard many times as water never spelled to souls like daughter.

It's the name of our magazine, the first addition to be published on Jan 26, 2021. Thank you Vaishali Singh

You have created a new word WAUGHTER for entire water and waste water afterbirth.
